JEDEC
STANDARD

Stress-Test-Driven Qualification of Integrated Circuits

JESD47J.01
(Revision of JESD47J, August 2017)

SEPTEMBER 2017

JEDEC SOLID STATE TECHNOLOGY ASSOCIATION
NOTICE

JEDEC standards and publications contain material that has been prepared, reviewed, and approved through the JEDEC Board of Directors level and subsequently reviewed and approved by the JEDEC legal counsel.

JEDEC standards and publications are designed to serve the public interest through eliminating misunderstandings between manufacturers and purchasers, facilitating interchangeability and improvement of products, and assisting the purchaser in selecting and obtaining with minimum delay the proper product for use by those other than JEDEC members, whether the standard is to be used either domestically or internationally.

JEDEC standards and publications are adopted without regard to whether or not their adoption may involve patents or articles, materials, or processes. By such action JEDEC does not assume any liability to any patent owner, nor does it assume any obligation whatever to parties adopting the JEDEC standards or publications.

The information included in JEDEC standards and publications represents a sound approach to product specification and application, principally from the solid state device manufacturer viewpoint. Within the JEDEC organization there are procedures whereby a JEDEC standard or publication may be further processed and ultimately become an ANSI standard.

No claims to be in conformance with this standard may be made unless all requirements stated in the standard are met.

Inquiries, comments, and suggestions relative to the content of this JEDEC standard or publication should be addressed to JEDEC at the address below, or refer to www.jedec.org under Standards and Documents for alternative contact information.

STRESS DRIVEN QUALIFICATION OF INTEGRATED CIRCUITS

(From JEDEC Board Ballot, JCB-17-09, formulated under the cognizance of the JC14.3 Subcommittee on Silicon Devices Reliability Qualification and Monitoring.)

1 Scope

This standard describes a baseline set of acceptance tests for use in qualifying electronic components as new products, a product family, or as products in a process which is being changed.

These tests are capable of stimulating and precipitating semiconductor device and packaging failures. The objective is to precipitate failures in an accelerated manner compared to use conditions. Failure Rate projections usually require larger sample sizes than are called out in qualification testing. For guidance on projecting failure rates, refer to JESD85 Methods for Calculating Failure Rates in Units of FITs. This qualification standard is aimed at a generic qualification for a range of use conditions, but is not applicable at extreme use conditions such as military applications, automotive under-the-hood applications, or uncontrolled avionics environments, nor does it address 2nd level reliability considerations, which are addressed in JEP150. Where specific use conditions are established, qualification testing tailored to meet those specific requirements can be developed, using JESD94 that will result in a better optimization of resources.

This set of tests should not be used indiscriminately. Each qualification project should be examined for:

a) Any potential new and unique failure mechanisms.

b) Any situations where these tests/conditions may induce invalid or overstress failures.

If it is known or suspected that failures either are due to new mechanisms or are uniquely induced by the severity of the test conditions, then the application of the test condition as stated is not recommended. Alternatively, new mechanisms or uniquely problematic stress levels should be addressed by building an understanding of the mechanism and its behavior with respect to accelerated stress conditions (Ref. JESD91, “Method for Developing Acceleration Models for Electronic Component Failure Mechanisms” and JESD94, “Application Specific Qualification using Knowledge Based Test Methodology”).

Consideration of PC board assembly-level effects may also be necessary. For guidance on this, refer to JEP150, Stress-Test-Driven Qualification of and Failure Mechanisms Associated with Assembled Solid State Surface-Mount Components.

This document does not relieve the supplier of the responsibility to assure that a product meets the complete set of its requirements.
2 Reference documents

The revision of the referenced documents shall be that which is in effect on the date of the qualification plan.

3 General requirements

3.1 Objective

The objective of this procedure is to ensure that the device to be qualified meets a generally accepted set of stress test driven qualification requirements. Qualification is aimed at components used in commercial or industrial operating environments.

3.2 Qualification family

While this specification may be used to qualify an individual component, it is designed to also qualify a family of similar components utilizing the same fabrication process, design rules, and similar circuits. The family qualification may also be applied to a package family where the construction is the same and only the size and number of leads differs. Interactive effects of the silicon and package shall be considered in applying family designations.

3.3 Lot requirements

Test samples shall comprise representative samples from the qualification family. Manufacturing variability and its impact on reliability shall be assessed. Where applicable the test samples will be composed of approximately equal numbers from at least three (3) nonconsecutive lots. Other appropriate means may be used to evaluate manufacturing variability. Sample size and pass/fail requirements are listed in Tables 1-3. Tables A and B give guidance on translating pass/fail requirements to larger sample sizes.

Generic data and larger sample sizes may be employed based upon a Chi Squared distribution using a total percent defective at a 90% confidence limit for the total required lot and sample size. ELFR requirements shall be assessed at a 60% confidence level as shown in Table B. If a single unique and expensive component is to be qualified, a reduced sample size qualification may be performed using 1/3 the sample size listed in the qualification tables.

3.4 Production requirements

All test samples shall be fabricated and assembled in the same production site and with the same production process for which the device and qualification family will be manufactured in production. Samples need to be processed through the full production process including burn-in, handling, test, and screening.

3.5 Reusability of test samples

Devices that have been used for nondestructive qualification tests may be used to populate other qualification tests. Devices that have been used in destructive qualification tests may not be used in subsequent qualification stresses except for engineering analysis. Non-destructive qualification tests are: Early Life Failure Rate, Electrical Parameters Assessment, External Visual, System Soft Error, and Physical Dimensions.
3.6 Definition of electrical test failure after stressing

Post-stress electrical failures are defined as those devices not meeting the individual device specification or other criteria specific to the environmental stress. If the cause of failure is due to causes unrelated to the test conditions, the failure shall be discounted.

3.7 Required stress tests for qualification

Table 1, Table 2, and Table 3 list the qualification requirements for new components. Table 2 and Table 3 are differentiated by package type, but these are not exclusively packaging tests. Interactive effects of the packaging on the silicon also drive the need for tests in Table 2 and Table 3. Power supply voltage for biased reliability stresses should be $V_{cc \ max}$ or $V_{dd \ max}$ as defined in the device datasheet as the maximum specified power supply operating voltage, usually the maximum power supply voltage is 5% to 10% higher than the nominal voltage. Some tests such as HTOL may allow for higher voltages to gain additional acceleration of stress time. JEP122 can provide guidance for accelerating common failure mechanisms.

Table 4 lists the required stresses for a qualification family or category of change. Interactive effects from the unchanged aspects of both the silicon and packaging must be assessed.

3.8 Pass/Fail criteria

Passing all appropriate qualification tests specified in Table 1, Table 2, and Table 3, either by performing the test, showing equivalent data with a larger sample size, or demonstrating acceptable generic data (using an equivalent total percent defective at a 90% confidence limit for the total required lot and sample size), qualifies the device per this document. When submitting test data from generic products or larger sample sizes to satisfy the Table 1, Table 2, and Table 3 qualification requirements of this document, the number of samples and the total number of defective devices occurring during those tests must satisfy 90% confidence level of a Poisson exponential binomial distribution, as defined in MIL-PRF 38535. MIL-PRF 38535 is available for free from http://www.dscc.dla.mil/Programs/MilSpec/listdocs.asp?BasicDoc=MIL-PRF-38535. The minimum number or samples for a given defect level can be approximated by the formula:

$$N >= 0.5 \left( \chi^2 (2C+2, 0.1) \right) \left[ 1/LTPD - 0.5 \right] + C$$

where $C =$ accept #, $N =$Minimum Sample Size, $\chi^2$ is the Chi Squared distribution value for a 90% CL, and LTPD is the desired 90% confidence defect level. Table A is based upon this formula, but in some cases the sample sizes are slightly smaller than MIL-PRF-38535.
3.8 Pass/Fail criteria (cont’d)

EXAMPLE: Using generic data for HTOL with a requirement of 0 rejects from 230 samples. If 700 samples of generic data are available, the maximum number of failures that will meet the qualification test requirement is 3 failures from the LTPD=1 column.

4 Qualification and requalification

4.1 Qualification of a new device

New or redesigned products (die revisions) manufactured in a currently qualified qualification family may be qualified using one (1) wafer/assembly lot. Electrical parameter assessment is one of the most important tests to run.

4.2 Requalification of a changed device

Requalification of a device will be required when the supplier makes a change to the product and/or process that could potentially impact the form, fit, function, quality and/or reliability of the device. The guidelines for requalification tests required are listed in Table 4.

4.2.1 Process change notification

Supplier will meet the requirements of JESD46 "Guidelines for User Notification of Product/Process Changes by Semiconductor Suppliers" for product/process notification changes.

4.2.2 Changes requiring requalification

All product/process changes should be evaluated against the guidelines listed in Table 4.
4.2 Requalification of a changed device (cont’d)

4.2.3 Criteria for passing requalification

Table 4 lists qualification plan guidelines for performing the appropriate Table 1, Table 2, and Table 3 stresses. Failed devices should be analyzed for root cause and correction; only a representative sample needs to be analyzed. Acceptable resolution of root cause and successful demonstration of corrective and preventive actions will constitute successful requalification of the device(s) affected by the change. The part and/or the qualification family can be qualified as long as containment of the problem is demonstrated until corrective and preventive actions are in place.

5 Qualification tests

5.1 General tests

Test details are given in Table 1, Table 2, and Table 3. Not all tests apply to all devices. Table 1 tests generally apply to design and fabrication process changes. Table 2 tests are for non-hermetic packaged devices, and Table 3 is for hermetic packaged devices. Table B lists the pass/fail requirements for common infant mortality levels. Table 4 gives guidance as to which tests are required for a given process change. Some of the data required may be substituted by generic process or package data.

5.2 Device specific tests

The following tests must be performed on the specific device to be qualified for all hermetic and organic packages. Passing or failing these tests qualifies or disqualifies only the device under qualification and not the associated qualification family:

1) Electrostatic Discharge (ESD) - All products - See Table 1.
2) Latch-up (LU) – Required for CMOS, BiCMOS, and Bipolar technologies. See Table 1.
3) Electrical Parameters Assessment - The supplier shall be capable of demonstrating, over the application temperature range, that the part is capable of meeting parametric limits in the individual device specification or data sheet.

5.3 Wearout reliability tests

Qualification family testing for the failure mechanisms listed below must be available upon request when a new wafer fabrication technology or a material relevant to the appropriate wearout failure mechanism is to be qualified. JP001 lists requirements for Fabrication Process Qualification. JEP122 explains how to project wearout lifetime for these failure mechanisms. The following mechanisms need to be considered, but there may be other mechanisms to consider based upon technology details.

- Electromigration; EM
- Time-Dependent Dielectric Breakdown; TDDB or Gate Oxide Integrity Test such as Charge to Breakdown.
- Hot Carrier Injection; HCI
- Negative Bias Temperature Instability; NBTI
- Stress Migration; SM, may be performed on an actual product.

The data, test method, calculations, and internal criteria need not be demonstrated or performed on the qualification of every new device.
5.4 Flammability/oxygen index

Certificates of compliance to UL94-0 or ASTM D2863 must be available upon request.

a) **HTOL** - The duration listed here is generally acceptable to qualify for the given Application Level. However, it does not necessarily imply the demonstration of the lifetime requirement for a particular use condition. It depends on failure mechanisms and application environments. For example, with apparent activation energy of 0.7 eV, 125 °C stress temperature and 55 °C use temperature, the acceleration factor (Arrhenius equation) is 78.6. This means 1000h stress duration is equivalent to 9 years of use. This might be shorter than the application requirement. In order to assure adequate lifetime requirement, it would be necessary to include Wafer Level Reliability Test information. Wafer Level Reliability can provide information about long term or intrinsic reliability of specific wearout mechanisms, the onset to failure time and design rule (e.g., maximum current density). For many failure mechanisms, such as dielectric breakdown, elevated voltage will provide additional acceleration and can be used to increase effective device hours or achieve an equivalent life point with a shorter stress duration. Refer to JEP122 for voltage acceleration models. Nonvolatile memory devices must be tested for proper operation after HTOL, but testing for data retention is optional (see Table 1a for nonvolatile memory data retention tests).
5.5 Device qualification requirements (cont’d)

b) **ELFR** - Several methods can be used to calculate the Early Life Failure Rate (ref. JESD74). The objective of ELFR is to measure the failure rate in the first several months or year of operation. Knowledge of the life distribution is generally required to accurately predict ELFR. Equivalently, Table B can be used to determine sample sizes to satisfy a particular FPM (cumulative failures) target. Voltage and temperature acceleration may be used to further accelerate effective unit hours. Nonvolatile memory devices must be tested for proper operation after ELFR, but testing for data retention is optional (see Table 1a for nonvolatile memory data retention tests).

c) **LTOL** – This requirement is aimed at Hot Carrier Degradation and may be satisfied by appropriate wafer level data as specified in JP001. This test is particularly useful when the wafer level data cannot demonstrate adequate life. This test should be run at the maximum frequency of the device with speed parameters data logged. Nonvolatile memory devices must be tested for proper operation after LTOL, but testing for data retention is optional (see Table 1a for nonvolatile memory data retention tests).

d) **HTSL** – High temperature storage may be accelerated by utilizing a higher temperature; however care must be taken that new failure mechanisms are not introduced such as Kirkendal Voiding at too high a temperature or suppressing failure mechanisms such as stress migration at temperatures above 180 °C. Alternatively, this test may be performed at the wafer level if packaged device reliability has been addressed with generic data. Nonvolatile memory devices must be tested for proper operation after HTSL, but testing for data retention is optional (see Table 1a for nonvolatile memory data retention tests).

e) **LU** – Verify $V_{cc}$ overvoltage and I/O trigger current resistance to latch-up per JESD78.

f) **ED** – This study is to be performed on key device parameters, it is not aimed at all datasheet parameters.

g) **ESD-HBM** Classification of Human body Model ESD sensitivity.

h) **ESD-CDM** Classification of Charge Device model ESD sensitivity.

i) **ASER** – Accelerated alpha particle and beam soft error testing may be utilized together to project the field soft error rate. For parts without $^{10}$ in the process, the only beam soft error testing required is high energy neutron or proton soft error testing; thermal neutron soft error beam testing is not required for such parts. This test is required for devices with a significant portion of the circuit utilizing volatile memory elements or latches. Generic data taken on products or test devices with similar memory elements or latches and equivalent critical charge may be substituted.

j) **SSER** – System soft error testing requires enough device hours to be accumulated to produce 10 failures or at least 1E6 device hours must be accumulated. High altitude testing may be used to accelerate this stress. This test may be utilized in lieu of or in addition to accelerated soft error testing. Generic data taken on products or test devices with similar memory elements or latches and equivalent critical charge may be substituted.

a) **UCHTDR** – Uncycled nonvolatile memories data retention failure mechanisms are generally accelerated by temperature and are modeled using the Arrhenius Equation for acceleration. The duration listed is generally acceptable for qualification but do not necessarily demonstrate the retention requirement for a particular use condition, which depends on failure mechanisms, acceleration factors and application environment. If the application requirement does not match the UCHTDR test’s retention values then a knowledge-based qualification should be followed (see JESD94). For devices specified to have some non-zero bit error rate, bit errors may not be counted towards device failure but must be shown to meet the bit error rate specification (see JESD22-A117).
5.5 Device qualification requirements (cont’d)

b) **NVCE** – See Figure 1 for linked flow for NVCE, PCHTDR and LTDR. Half of the devices are cycled at room temperature and half at elevated temperature. **Quantity of Cycling:** Cycling should be performed to the max spec. cycle count on 50% of cells and to 10% of max spec. cycle count on the other 50% of cells when this is possible within 500 hours. For large memories where this would be impossible, the total program/erase operations are to be the number possible in 500 hours. This will be accomplished by reducing the fraction of cells cycled to max spec. and increasing the fraction cycled to 10% of max spec. In some cases it will be necessary to cycle some fraction of cells to less than 10% of max spec. to ensure that all cells receive some cycling. At least one-third of the operations should be devoted to cycling blocks to 100% of maximum specification. For multi-block memories, at least one block of each device must be cycled to the max. spec. cycle count, regardless of the time required. Such cycling conditions are generally acceptable also for system implementing wear leveling; otherwise, a knowledge based qualification can be implemented. **Delays between Cycles:** The supplier may specify that cycling not exceed a certain rate per day or that delays or bakes be inserted between cycles, to avoid overstress due to unrealistic conditions or to emulate delays expected in intended application, subject to four constraints. First, the quantity of cycling is for 500 hours of actual cycling operations, not counting inserted delays. Second, inserted delays must be distributed per the guideline in JESD22-A117. Third, for room-temperature cycling, no high-temperature delays are to be inserted. Fourth, for high-temperature cycling, the delays plus the cycling time itself must not add up to more than 500 hours at 85 °C (longer delays acceptable at lower temperatures per JESD22-A117, 4.1.2.4). These delays do not necessarily demonstrate the effect that would be seen with a particular use condition. For example, with apparent activation energy of 1.1 eV for dielectric charge detrapping, the delay durations are equivalent to 1.5 years of cycling at 55 °C. An application condition with less delay would be more severe than is represented by the qualification delays specified above. If application use conditions deviate considerably from the cycle counts or equivalent times described above, then an application-specific qualification methodology can be pursued per JESD94. For devices operated with Bad Block Management and specified to have a non-zero bad-block rate, a unit with blocks failing program/erase is to be counted as a failure if the number of such blocks exceeds the allowed bad-block specification (see JESD22-A117, 2.5). For devices specified to have some non-zero bit error rate, bit errors are not to be counted towards device failure but must be shown to meet the bit error rate specification (see JESD22-A117, 2.8, and 5.2).

c) **PCHTDR** – See Figure 1 for linked flow for NVCE, PCHTDR and LTDR. The NVCE devices cycled at elevated temperature are placed in high-temperature retention bake. Two options are given, either of which is acceptable for qualification, and for each option two bake durations. The longer of the two durations is to be applied to the blocks cycled to ≤ 10% of the max. spec. cycles. The shorter of the two is to be applied to blocks cycled to 100% of max. spec. cycles. For example option 2 requires that blocks cycled to ≤ 10% of max. spec. cycles retain data for 100 hours of 125 °C (FG-CT)/100 °C (PCM) bake, and blocks cycled to 100% of max. spec. cycles must retain data for 10 hours of 125 °C (FG-CT)/100 °C (PCM) bake. The durations listed are generally acceptable for qualification but do not necessarily demonstrate the retention requirement for a particular use condition, which depends on failure mechanisms and application environments. For example, with activation energy of 1.1 eV for dielectric charge detrapping, 125 °C stress temperature (option 2) and 55 °C use temperature, the acceleration factor (Arrhenius equation) is 939. Bake time is then equivalent to 11.3 years for 10% of max. spec. cycles and 1.1 years for 100% of max. spec. Retention lifetime necessary in use will be less than total product lifetime, because the PCHTDR requirement is a sequential reliability stress that is preceded by up to one lifetime’s worth of endurance cycling (NVCE). If the application requirement does not match these retention values, or the technology has different activation energy, then a knowledge-based qualification should be followed (see JESD94). For devices specified to have some non-zero bit error rate, bit errors may not be counted towards device failure but must be shown to meet the bit error rate specification (see JESD22-A117).
### 5.5 Device qualification requirements (cont’d)

d) **LTDR** – See Figure 1 for linked flow for NVCE, PCHTDR and LTDR. The NVCE Devices cycled at room temperature are placed into room-temperature operating-life stress which sequentially performs dynamic read accesses on all memory addresses. 25 °C stress temperature is used to determine sensitivity to non-temperature-accelerated retention failure mechanisms, or to mechanisms that can entirely recover at high temperatures, such as the SILC mechanism. Biased life stress is performed to detect voltage-induced disturbs due to random bit accesses, in addition to unbiased data retention mechanisms which occur when a bit is not being accessed. Inserted bakes as described for NVCE are not acceptable for the 25 °C cycling condition used prior to LTDR. If the cycle counts from note (b) or the retention lifetimes of 500 hours are insufficient to meet a specific application requirement, or if bit accesses in application are expected to be highly concentrated on specific bits, then knowledge-based qualification methods using special techniques should be used (see JESD94). For devices specified to have some non-zero bit error rate, bit errors may not be counted towards device failure but must be shown to meet the bit error rate specification (see JESD22-A117).

5.6 Nonhermetic package qualification test requirements (cont’d)

Notes to Table 2 — Qualification tests for components in nonhermetic packages

NOTE 1 Preconditioning to JESD22-A113 is recommended, specifically for wire-bonded products qualified to Pb-free reflow profiles. Moisture soak as part of the preconditioning is optional.

NOTE 2 Either HAST or THB may be chosen.

NOTE 3 If THB or HAST is run, then UHAST need not be run.

NOTE 4 It is recommended that the Temperature Cycling condition is chosen applying the following criteria:
- Condition G, B or C may not be appropriate unless the device will be subjected to a sub 0 °C cycle in its routine field operating life.
- Condition G, B or C may not be appropriate for Flip Chip packages with organic substrates.
- The condition chosen must encompass the range that device will be subjected to in its routine field operating life.
- Annex A explains the failure mechanisms and models used for the choice of temperature cycling conditions.
- Any Temperature Cycling condition specified in JESD22-A104 may be used following the methodology in Annex A.

NOTE 5 Autoclave is not recommended as a qualification test; Unbiased or biased HAST is the recommended stress and is required for organic substrates instead of Autoclave.

NOTE 6 \[ P_{pk} = \frac{\bar{x} - LSL}{3\sigma}, \quad \frac{USL - \bar{x}}{3\sigma} \geq 1.66 \] Process capability data may be substituted for Ppk with data on more than 30 lots with the requirement that \( C_{pk} \geq 1.33 \).

NOTE 7 See 7.1 for Bond Shear and 7.3 for Bond Pull Strength failure criteria.

CONDITIONS:

A) HTSL This test is basically used to determine if the effects of diffusion, oxidation, intermetallic growth, and chemical degradation of packaging components will affect product life.

B) THB will accelerate the three basic corrosion models: Galvanic, Electrochemical and direct Chemical. It will also accelerate ion migration. Must be run at minimum power dissipation.

C) HAST is a test used to accelerate the THB test. Must be run at minimum power dissipation. It is suggested that 130 °C for 96 hours be used for leaded devices and 110 °C for 264 hours be used for Ball Grid Arrays.

D) TC will accelerate damage caused by thermal-mechanical stress as a result of thermal mismatch and dimensional differences.

E) UHAST is the preferred technique to test for Galvanic and direct Chemical corrosion.

F) AC (Autoclave) is the less desirable alternative to UHAST testing. It can introduce condensation and pressure induced mechanical damage that are not representative of package field life stresses. Autoclave is not recommended for organic substrate packages.

G) PC (Pre-Conditioning) ensures that a device will be able to withstand multiple assembly cycles, and to simulate the stress from Printed Circuit Board assembly that a device in a field operation would receive prior to acceleration stress testing.

H) SBS (Solder Ball Shear) ensures that the BGA balls have the desired shear strength attachment to the package.

I) BPS (Bond Pull Strength) ensures that wire bond exhibits the desired tensile strength. See 7.3 for failure criteria.

J) BS (Bond Shear) ensures that the wire ball bond exhibits the desired shear strength. See 7.1 for failure criteria.

K) SD (Solderability) ensures that the device leads are capable of being wetted by the board attachment solder.

L) WSR (Tin Whisker Susceptibility) for use when tin (Sn) or tin alloy surface finishes are used. This acceptance procedure provides a basis for comparison between surface finishes with respect to the propensity for whisker growth, but does not provide a basis for prediction of whisker growth in field use conditions.
5.7 Hermetic package qualification tests

These packages are typically used in long term applications and severe environments so some requirements may be different than for non-hermetic packages.

NOTE 4 See 7.1 for Bond Shear and 7.3 for Bond Pull Strength failure criteria.

5.8 Results are to be reported in accordance with JESD69.
6 Explanatory comments regarding process/product changes

6.1 The following changes require re-qualification:

Active Circuit Element: New type of circuit element or modification of transistors beyond original qualification or spec limits.

Major Circuit Elements: Addition of a major new circuit block to an existing circuit such as adding a Digital Signal Processor or embedded memory block to an existing product.

Wafer Diameter Change

Metallization: New Materials or a significant change in composition

Change In Minimum Feature Size: A reduction of greater than 20% shall be considered a new process.

Wafer Fab Process: Utilizing different process techniques at critical points (excluding wafer transport equipment)

Diffusion/Dopant: New material or technique

Poly-silicon or other MOSFET gate material: Composition, design rules, process

Lithography: Change in wavelength, method (air / immersion / ebeam), or etch technique

Wafer Frontside Metallization: Composition, design rules, process and/or technique

VIA: Composition, design rules, process and/or technique

Passivation Overcoat: Either glass or organic material composition, design rules, process and/or technique

Dielectric Materials: Composition, design rules, process and/or technique

Low-K Dielectric: A dielectric material used for inter-metal isolation with a K value less than 3.2.

Wafer Backside Operation: Metal composition, design rules, process and/or technique

New Wafer Manufacturing Line: Not already qualified for the fabrication process

Assembly Process: Utilizing different process techniques at critical points

Die Coating: Material, process, and/or technique

Lead Frame: Base material, finish, and critical dimensions

Bond Wire: Material, diameter

Bonding: Process and/or technique

Die Preparation: Separation and clean methods

Die Attach: Material, process, and/or technique

Encapsulation: Material, composition, process and/or technique

Hermetic Package: Material, composition, seal material, process and/or technique

Wafer Bumping Material: process, or technique (including flip chip assembly process)

Package Dimension Change: Larger package body size or reduction in lead or solder ball pitch.

Die Thickness

New Chip-Package Combination
6.2 Changes that may not require re-qualification

Assembly location already qualified for that package.

The movement of product manufacturing (wafer fab or assembly) from one location to another where the new location is already qualified for the same process and techniques requires only completion of manufacturability tests at the new location.

The addition of previously qualified equipment requires completion of process capability study only, to assure that the added equipment delivers an adequate process distribution.

A change to a test program or test equipment requires proof of continued conformance to product specification only.

Any change in a process, product or material parameter that does not exceed the current specified production process range is not a major change.

Minor changes to device logic operation may only require functional verification.

Smaller package or die where the product family has already been qualified.

6.3 Multiple family qualifications

When the specific product attribute to be qualified will affect more than one wafer fab or assembly family, the qualification test vehicles should be:

1) One lot of a single device type from each of the three (3) products that are projected to be most sensitive to the changed attribute, or
2) Three lots total from the most sensitive families if only one or two exist.

Below is the recommended process for qualifying changes across many process and product families:

1) Identify all products affected by the proposed changes.
2) Identify the critical structures and interfaces potentially affected by the proposed change.
3) Identify and list the potential failure mechanisms and associated failure modes for the critical structures and interfaces. Note that steps 1 to 3 are equivalent to the creation of an FMEA.
4) Define the product groupings or families based upon similar characteristics as they relate to the structures and device sensitivities to be evaluated, and provide technical justification for these groupings.
5) Provide the qualification test plan, including a description of the change, the matrix of tests and the representative products that will address each of the potential failure mechanisms and associated failure modes.
6) Robust process capability must be demonstrated at each site (e.g., control of each process step, capability of each piece of equipment involved in the process, equivalence of the process step-by-step across all affected sites) for each of the affected process steps.
### 6.4 Guidelines for stress tests for typical process changes

Table 4 lists the recommended (R) qualification tests for each type of change in the process, package, or device design, and additional tests that should be considered (C) based upon technology considerations.

**Table 4 — Guidelines for major process change selection of tests**

| Process Attribute | Active Circuit Element | Major Circuit Change | 5% to 20% Die Shrink | Lithography | Doping | Polysilicon | Metallization | Gate Oxide | Interlayer Dielectric Non low-k | Low-K Dielectric | Passivation | Contact | Via | Wafer diameter | New Package to Qualified Product | Leadframe plating¹ | Leadframe Material | Package Dimensions, including trace pitch | Wire Bonding | Multi-Chip Module Die Separation | Molding Compound | Package Substrate Material | Package Substrate Plating | Molding Process | Assembly Site | Burn-in Elimination | Burn-in Reduction** | Flip Chip Attach Method | Wafer Bump Materials or Process | Wafer Bump Under-Metal | Bump Site | Flip Chip Underfill | Die thickness |

R – Recommended<sup>1</sup>  * - Measure material alpha emissivity  
C – Consider<sup>1</sup>  ** - May be based upon defect density reduction with justification  

**NOTE 1** Additional consideration may be necessary when evaluating product changes with respect to tin whiskers. Consult JESD201 when making changes involving high tin content materials. A separate table is located in JESD201 that addresses whisker test requirements based on various types of changes.
7 Wire bond qualification requirements

7.1 Failure criteria for wire bond shear test method (JESD22-B116) of unencapsulated and unstressed bonds

The following failure criteria are intended to be applied as a production monitor of the wire bonding process as well as for qualification and process development. They are not valid for devices that have undergone environmental stress testing, have been desoldered from circuit boards, or were preconditioned (some procurement or qualification documents require that the samples be preconditioned prior to the performing of this test method).

Please refer to Clause 4.6 of JESD22-B116 for guidance on acceptable and non-acceptable fail modes.

7.1.1 Shear failure criteria for gold and copper ball bonds on aluminum bond pads

The equation below is applicable for “gold” and “copper” wire ball bonds on aluminum alloy bond pads. “Gold” wire includes doped gold wire. “Copper” wire includes palladium coated copper, palladium coated copper with gold flash, and doped copper wires.

The determination of whether a shear value is acceptable is determined by using the equation below.

\[
\text{measured shear force value} + \text{ball bond area} \geq 0.0062 \text{ gf/} \mu \text{m}^2
\]

The above shear failure criteria shall be applied to all copper ball bonds on aluminum bond pads. This criteria shall also be applied to all new device qualifications with gold ball bonds on aluminum bond pads. Previously qualified devices with gold ball bonds on aluminum bond pads may either meet the above criteria or the previous criteria stated in Table 1 of JESD-B116A (August 2009).

If alternate units of force or area are used for this test, the value of 0.0062 gf/\(\mu \text{m}^2\) shall be replaced with one of the following appropriate conversions: 61 N/mm\(^2\) or 4.0 gf/mil\(^2\).

Alternate minimum bond shear values may be proposed by the supplier if supporting data justifies the proposed minimum values and the customer agrees.

Other material combinations (wire and/or bonding surface) may require a new set of failure criteria.

7.1.2 Shear failure criteria for gold and copper ball bonds on copper base metal bonding surfaces

At the time of the most recent revision of this document there was not enough data available to propose a value for acceptable shear force for gold or copper ball bonds on copper base metal bonding surfaces.

7.2 Failure criteria for wire bond shear test method (JESD22-B116) for encapsulated and stressed bonds

There is too much variability between device construction, decapsulation processes, and stress conditions for this document to propose failure criteria for the shearing of ball bonds that have been decapsulated or have been exposed to production or qualification stresses.
7.3 Failure criteria for wire bond pull testing (Mil-Std 883, Method 2011)

At the time of the most recent revision of this document there was not enough data available to propose a value for acceptable pull force for copper wire bonds. The failure criteria for unstressed, unencapsulated gold bond wires currently reside within Mil-Std 883, Method 2011.
Annex A (informative) Nonhermetic package temperature cycling requirements

Solder joint Reliability is generally the limiting factor for component life in a system subjected to temperature cycling. Solder joint life is well modeled by a Coffin-Manson relation of $\Delta T^n$ where $n=2$. Other failure mechanisms as reported in JEP122 have larger acceleration factors so this becomes a worst case condition. The temperature cycling requirements have been normalized to the historical requirement of 500 cycles of Condition C using the n=2 factor. As a sanity check the typical use conditions for a number of common applications have been compared to these qualification conditions. As can been seen in the table below the qualification requirements exceed the use conditions by a wide margin.

<table>
<thead>
<tr>

### B.1 Differences between JESD47J and JESD47I.01 (October 2016)

<table>
<thead>
<tr>
<th>Clause</th>
<th>Description of Change</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.6</td>
<td>In Table 2 modified sample requirement for wire pull and bond shear to be from 1 Lot which now matches requirement in Table 3. Added Footnote 7 which states that failure criteria for bond pull strength and bond shear are in new subclauses 7.3 and 7.1 respectively.</td>
</tr>
<tr>
<td>5.7</td>
<td>Added Footnote 4 which states that failure criteria for bond pull strength and bond shear are in subclauses 7.3 and 7.1 respectively.</td>
</tr>
<tr>
<td>6.4</td>
<td>Added “C” (Consider) for THB/HAST stress for Wire Bonding.</td>
</tr>
<tr>
<td>7</td>
<td>Added new clause 7, “Wire bond qualification requirements”. Subclause 7.1 states the failure criteria for the bond shear test for both gold and copper ball bonds on aluminum bond pads. Subclause 7.2 provides guidance for performing shear testing on bonds that have been encapsulated or stressed. Subclause 7.3 provides guidance regarding the failure criteria for the wire pull test method.</td>
</tr>
</tbody>
</table>

### B.2 Differences between JESD47I.01 and JESD47I (July 2012)

<table>
<thead>
<tr>
<th>Clause</th>
<th>Description of Change</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.5</td>
<td>Table 1 CDM spec reference changed to JS-002 from JESD22-C101</td>
</tr>
<tr>
<td>5.5</td>
<td>Changed “resistance” to “sensitivity” in notes g) and h)</td>
</tr>
<tr>
<td>5.6</td>
<td>Table 2 Solderability spec reference changed to J-STD-002 from JESD22-B102</td>
</tr>
<tr>
<td>5.7</td>
<td>Table 3 Solderability spec reference changed to J-STD-002 from JESD22-B102</td>
</tr>
</tbody>
</table>

### B.3 Differences between JESD47I and JESD47H.01 (April 2011)

<table>
<thead>
<tr>
<th>Clause</th>
<th>Description of Change</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Added material to 2\textsuperscript{nd} and 5\textsuperscript{th} paragraph and removed material in Scope</td>
</tr>
<tr>
<td>5.5</td>
<td>add last sentence to a), b), c), and d)</td>
</tr>
<tr>
<td>Figure 1</td>
<td>Added details for PCM</td>
</tr>
<tr>
<td>Global</td>
<td>changed Ta to T_A and changed Tj to T_j</td>
</tr>
</tbody>
</table>
B.4 Differences between JESD47H.01 and JESD47H

Clause Description of Change

Table 1 Updated Human Body Model reference from JESD22A-114 to JS-001

B.5 Differences between JESD47H and JESD47G.01

Clause Description of Change

Table 1 UpdatedLatchup requirements to align with latest revision of JESD78

B.6 Differences between JESD47G.01 and JESD47G

Clause Description of Change

Table 1 Under latch-up changed Conditions, from $T_A=25\, ^\circ\text{C}$ and $T_{j_{\text{max}}}$ to Class I or Class II.

5.5(h) Added “per JESD78” to end of sentence.

B.7 Differences between JESD47G and JESD47F

Clause Description of Change

7 In Table 1, NVCE, change temperature range to $85\, ^\circ\text{C} \geq T_j \geq 55\, ^\circ\text{C}$ and add fail criteria (0 fails)

7 In Table 1, LTDR, change reference document to JESD22-A117

7 In Table 1, NVCE, HTDR and LTDR entries, add number of note.

8 note (e): Specify fraction of device that needs to be cycled 100%, 10% and less than 10% of endurance spec. Specify constrains for delays between cycles

9 note (e): In definition of failure, add consideration of Bad Block management and allowed bit-error rate.

9 note (f), (g): In definition of failure, add consideration of allowed bit-error rate

10 Figure: Set NVCE temperature range to $85\, ^\circ\text{C} \geq T_j \geq 55\, ^\circ\text{C}$, remove table redundant to note (e),

B.8 Differences between JESD47F and JESD47E

Clause Description of Change

2.2 Added references, JESD201 and JESD22A121

Table 2 Added “Tin Whisker Acceptance” row

Table 3 Added “Tin Whisker Acceptance” row

6.4, Table 4 Under “New package to Qualified Product”, changed ESD-HBM from “R” to blank (no requirements) and ESD-CDM from “R” to “C”. Added reference 1 below table.
B.9 Differences between JESD47E and JESD47D (November 2004)

JESD47E is a complete rewrite of the Specification for Stress Driven Qualification of Integrated Circuits. Every section was upgraded. This document lists the major changes by section. Many changes are for clarification or to conform to current JEDEC specification formats.

1. **Scope:** Updated references to allied JEDEC documents that address similar issues.
2. **Reference Documents:** A more complete and current list is provided.
3. **General Requirements:** Clarifies using family qualification and generic data. Breaks up qualification into Silicon and Package Requirements. Clarifies use of $X^2$ distribution for generic and larger sample sizes. Gives guidance on the use of accelerated voltage stressing in addition to temperature.
4. **Qualification and Requalification:** No major changes
5. **Qualification Tests:** Test information is organized by fabrication process and package requirements. Information regarding a test is contained within a single table. More extensive reference to requirements for wearout testing and reference to JP001 Fabrication Process Qualification. Sample sizes were reduced for many tests that are intrinsic wearout mechanisms. The traditional 77 piece per lot sample size was only retained for lifetest and nonvolatile memory endurance for which defect mechanisms are significant contributors to the observed failure rate.

Extensive notes were added to explain test methodologies.
   a. **Early Life Failure Testing:** The methodology was specified and requirements were enumerated in Table B.
   b. **Low Temperature Operating Life:** Minimum temperature was raised max frequency operation required, can be replaced by wafer level HCI testing.
   c. **NonVolatil memory:** Endurance and Data Retention methodology was changed along with test method JESD22-A117 and JEP122.
   d. **Preconditioning:** Is now required before all package tests
   e. **Temperature Cycling:** Requirements were changed for all conditions except condition “C”.
   f. **Autoclave:** No longer recommended, especially for BGAs.
   g. **Power Temperature Cycling no longer required
   h. **Explained Cpk vs Ppk
6. **Process/Product Changes:** Improved explanation of changes requiring requalification and testing required.
7. **Annex A:** Added to explain change in component temperature cycling requirements.
Standard Improvement Form

JEDEC JESD47J.01

The purpose of this form is to provide the Technical Committees of JEDEC with input from the industry regarding usage of the subject standard. Individuals or companies are invited to submit comments to JEDEC. All comments will be collected and dispersed to the appropriate committee(s).

If you can provide input, please complete this form and return to:
JEDEC
Attn: Publications Department
3103 North 10th Street, Suite 240 South
Arlington, VA 22201
Fax: 703.907.7583

1. I recommend changes to the following:
   [ ] Requirement, clause number
   [ ] Test method number
   [ ] Clause number
   [ ] Other

   The referenced clause number has proven to be:
   [ ] Unclear
   [ ] Too Rigid
   [ ] In Error
   [ ] Other

2. Recommendations for correction:
   ______________________________________________________
   ______________________________________________________
   ______________________________________________________
   ______________________________________________________

3. Other suggestions for document improvement:
   ______________________________________________________
   ______________________________________________________
   ______________________________________________________
   ______________________________________________________
